

(c) How each record measures it

Aerial photos

24 dated surveys, 1967-2023; one day each. Each side's position is the mean distance from the wet/dry line to a fixed offshore datum line (25 points per domain), as change since 1967. Gap = south's retreat − north's retreat.

CoastSat

satellite shorelines from 1984, many images a year. Each transect's yearly mean (≥ 3 images), about its own 1984-2016 mean, averaged over the side (6 transects in GIS 6, 13 in GIS 5). Gap = north − south. With no 1967 survey, only its changes compare, so it is moved onto the photos' 1967 baseline.

Reading it

rising: the north holds while the south retreats (the groin trapping sand); flat: the groin holds the gap but adds nothing; falling: the two sides converge (sand getting past the groin, or a storm or fill on one side).
