Where the wave-driven groin sits in the model

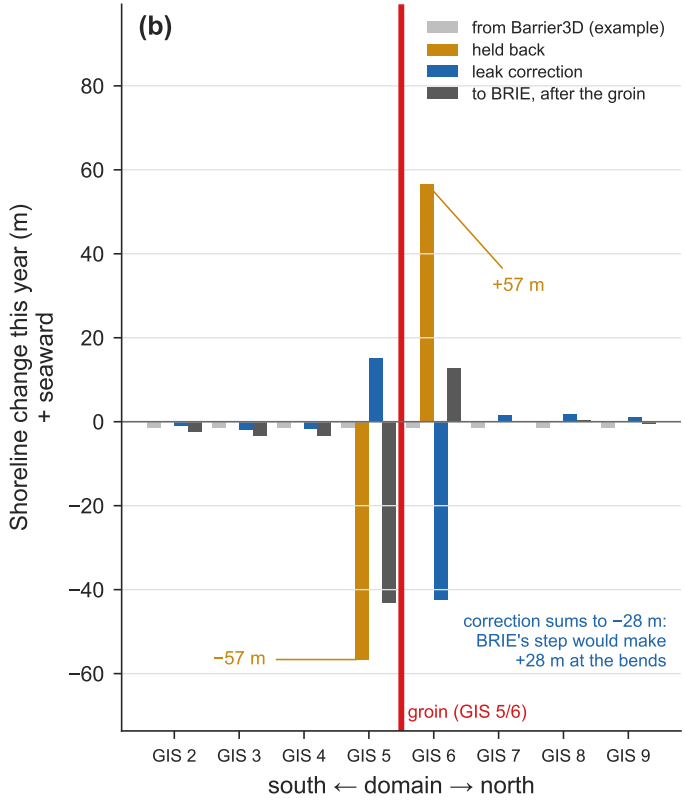
One model year, in order

(a)

1. Barrier3D runs in every domain
storms, overwash, dunes and its background erosion (BE)
→ each domain's shoreline change this year

2. The wave-driven groin edits that change, in two parts
held back: a share of the drift arriving at the groin,
read from the waves each year, moved GIS 5 → GIS 6
leak correction: within 10 domains of the groin, cancels
the sand BRIE's step would make or lose at its bends

3. BRIE moves the shoreline alongshore, unchanged
it smooths the edited shoreline between neighbouring domains;
with step 2's correction the island's sand balances

next year


What step 2 does (year 10, coast at −20°)
